

Notion × ClickUp Integration

Systems design for a five-scenario Make.com automation synchronising a personal Notion workspace with ClickUp task execution

Project Status: Planning Complete — Implementation Pending Date: June 2026

Summary

A detailed integration design — comprising a Product Requirements Document and a module-level build specification — for a Make.com workflow that keeps a personal Notion workspace and a ClickUp workspace in sync. The planning artefacts are complete; the Make.com scenarios and workspace configuration have not yet been implemented.

The Problem

Knowledge workers who rely on Notion for structured planning and ClickUp for task execution must manually duplicate information across both tools. A project defined in Notion must be re-entered in ClickUp; status changes made in ClickUp must be hand-copied back. This friction introduces errors, delays, and cognitive overhead — particularly for a solo operator managing multiple concurrent projects.

Objective

Design and specify a one-directional-primary integration (Notion → ClickUp for project and task creation; ClickUp → Notion for status and completion updates) using five Make.com scenarios, seven Notion databases, and a ClickUp workspace structure. The integration should require no manual data entry after initial project creation, and should surface completion dates in Notion automatically when tasks are closed in ClickUp.

Intended Users

A solo knowledge worker ('Yogi' — named explicitly as the sole stakeholder in the PRD) managing personal and professional projects. The system is designed for single-user operation; multi-user support is listed as out of scope and flagged as a scaling risk.

Why This Matters

Integrating planning tools without writing custom code is an increasingly common pattern in personal productivity and small-team operations. Make.com (and similar low-code automation platforms) allow complex, event-driven workflows to be built and maintained by non-developers. This project demonstrates how thorough upfront specification — produced before any automation is built — reduces ambiguity and enables faster, lower-risk implementation. The design discipline shown here (risk registers, open-item tracking, module-level scenario specs) reflects professional systems-design practice applied to personal tooling.

Architecture and End-to-End Workflow

Four-layer architecture:

End-to-end workflow (primary path):

1. New project created in Notion with status "Active"
2. S-01 poll (≤15 min) detects it → creates ClickUp Folder + 3 Lists
→ writes ClickUp URL back to Notion project page
3. Deliverable set to "Ready for Execution" in Notion
4. S-02 poll (≤15 min) detects it → creates ClickUp task
→ writes ClickUp task URL to Notion deliverable
5. Task status updated in ClickUp
6. S-03 webhook (≤30 s) fires → updates Notion deliverable Status field
7. Task marked Complete in ClickUp
8. S-04 webhook fires → stamps Notion "Completion Date" field with today
9. S-05 runs Monday 06:00 → creates Notion Weekly Review page
→ sends email notification

Technologies Used

Technology	Version	Role
Make.com	Core plan	Integration automation — all 5 scenarios
Notion API	v2	Database reads/writes (projects, deliverables, review)
ClickUp API	v2 + webhooks	Folder/list/task creation; status-change webhooks
Node.js	v20 (inferred)	Document generator runtime
docx	^9.7.1	DOCX document generation (planning artefacts only)
Google Drive	—	Automated backup destination (Notion exports, ClickUp CSVs)

What Was Actually Built

Each capability is independently labelled based on evidence found in the repository.

Capability	Status
PRD v2.1 (design document, Jun 2026)	Implemented
Integration Spec v1.0 (module-level build spec)	Implemented
Node.js DOCX generator scripts (create_prd.js, create_integration_spec.js)	Implemented
Seven Notion database schemas with full field definitions	Planned
ClickUp workspace structure (Space, Folder, List naming conventions)	Planned
S-01 New Project Sync (Notion → ClickUp, polling 15 min)	Planned
S-02 Task Push (Notion → ClickUp, polling 15 min)	Planned
S-03 Status Sync (ClickUp → Notion, webhook ≤30 s)	Planned
S-04 Completion Date Sync (ClickUp → Notion, webhook)	Planned
S-05 Weekly Review Generator (Monday 06:00, scheduled)	Planned
Idempotency check on S-01 (folder-search before create)	Planned
Error logging to Notion 'Integration Errors' database	Planned
Reconciliation log for unmatched task completions	Planned
Google Drive automated backup (Sun/Tue/Thu)	Planned
Make.com scenario blueprint exports (JSON files)	Not present
Any working API integration code	Not present
Automated test execution	Not present

Implementation Notes

Both planning documents were produced on 9 June 2026 within approximately 30 minutes of each other (file timestamps 17:26 and 17:52 UTC). The PRD runs to twelve sections — including a version history, risk register, twelve open items (seven resolved, five open), and a six-phase SDLC plan. The Integration Spec provides module-by-module build tables for all five scenarios, precise field-mapping references, a ten-item test checklist, and a three-gate go-live checklist. The specification is granular enough to serve directly as build instructions without further design work.

The 'notion_clickup_integration/' directory itself is empty; the planning artefacts reside in an adjacent 'outputs/' directory. No git history is present in either location. There are no exported Make.com blueprint JSON files, no screenshots of configured workspaces, and no API integration code anywhere in the repository.

User Contribution and Role

The user ('Yogi') is the sole author of all planning content. All roles in the PRD — System Owner, Integration Owner, Project Lead, Quality Reviewer — are assigned to the same individual. The document generator scripts are authored by the user. The system was designed from scratch; no upstream template or framework was used.

Testing and Validation Evidence

The Integration Spec defines ten unit test specifications (UT-01 to UT-10) with concrete pass criteria for each scenario. For example, UT-01 requires that a new project created in Notion causes a ClickUp folder and three lists to appear within 15 minutes, with the ClickUp URL written back to Notion. The test checklist contains a pass/fail column that is entirely blank — no tests have been executed. There is no test runner, no CI pipeline, and no test output anywhere in the repository.

Known Limitations

- 15-minute polling lag on S-01 and S-02 — inherent to Make.com's polling trigger; not a bug but a design constraint noted in the spec.
- Notion AI (used in S-05 meeting summaries) requires a paid Notion AI add-on (~£8/user/month) — flagged in a 'FLAG' callout in the PRD.
- Single-owner system — all roles assigned to one person; flagged as Risk R-06 with planned mitigation (documentation).
- Five open items (OI-08 to OI-12) unresolved in the PRD baseline.
- Rate-limit sleeps (300 ms in S-02, 200 ms in S-03) are estimates, not values validated against actual API throttling behaviour.
- ClickUp Unlimited plan required for workspace-level custom fields — a paid-tier prerequisite before Phase 1.
- Second Brain 3.0 adaptation path adds an extra Notion API call and a potential Make.com Data Store lookup in S-01.

Lessons Learned

The project demonstrates that specification work at module level — rather than at scenario level — removes the primary source of implementation ambiguity in Make.com builds. By defining each module's inputs, outputs, filters, and mappers in the spec, the build becomes a configuration exercise rather than a design exercise. The risk register and open-item tracker embedded in the PRD are evidence of a disciplined approach to managing design debt before implementation begins.

Practical Next Steps

1. Set up the Notion workspace following Integration Spec §3 (seven database schemas, property types, and relations).
2. Configure the ClickUp workspace (Space, naming conventions, 'Notion Page URL' custom field at space level).
3. Build S-01 first in Make.com — it is the dependency for all downstream scenarios.
4. Export Make.com blueprint JSON files to the repository after each scenario is built.
5. Execute the ten unit tests (UT-01 to UT-10) and record pass/fail status in the spec.
6. Resolve the five open items (OI-08 to OI-12) before advancing beyond Phase 1.

Evidence Base Reviewed

- outputs/create_prd.js (964 lines, Node.js DOCX generator)
- outputs/create_integration_spec.js (713 lines, Node.js DOCX generator)
- outputs/Notion_ClickUp_PRD_v2.docx (40 KB, Jun 9 2026 17:26 UTC)
- outputs/Notion_ClickUp_Integration_Spec_v1.0.docx (32 KB, Jun 9 2026 17:52 UTC)
- outputs/package.json (docx ^9.7.1, Node.js runtime)
- notion_clickup_integration/ directory — confirmed empty
- No git repository found in any path reviewed
